

Sources For Clinical Outcome Reporting And Assessments

In a recent survey of respondents familiar with eCOA and ePRO systems, ISR asked about respondents' past and projected use patterns regarding both the source of clinical reported outcomes, and the source of clinical outcomes assessments (COAs.) Device-based interfaces continue to gain popularity over non-device-based sources, and projected use seems to follow that trend, with respondents expecting an increase of 13 percentage points. As for those who input COAs into those interfaces, respondents reported that patients are expected to be the leading source of COAs over clinicians and caregivers/observers.

“Over the past two years, what percent of reported outcomes have come from the following sources? What will the percent be for each source over the next two years? Your best estimates are fine, but percentages must sum to 100.” (n=118)
